with $x \, 2 \, \mathbb{R}^n$ [3]. We can write the 4D-Var objective function (1) in this form by putting $f(x) = C^{-1=2} \hat{d}$, where

$$
\hat{\mathbf{d}}(\mathbf{x}_0) = \mathbf{i} \begin{bmatrix} \mathbf{x}_0 & \mathbf{i} & \mathbf{x}^b & 1 \\ \frac{\mathbf{d}}{\mathbf{d}} & H_0[\mathbf{x}_0] & \mathbf{j} & \mathbf{y}_0^o \\ \vdots & \mathbf{k} & \mathbf{c}^{-1} \end{bmatrix} = \begin{bmatrix} \mathbf{B}_0^{-1} & \mathbf{0} & \mathbf{0} \\ \mathbf{B}_0^{-1} & \mathbf{0} & \mathbf{R}^{-1} \end{bmatrix}
$$
 with $\mathbf{R} = \text{diag}f\mathbf{R}_i g$.

Figure 1: Comparison of convergence of (a) objective function and (b) its gradient for a constant convergence criterion (solid line) and a variable criterion (dashed line).

with $D=Dt = e^{\theta} = e^{\theta}t + u^{\theta} = e^{\theta}x$. In these equations $\bar{h} = \bar{h}(x)$ is the height of the bottom orography, u is the velocity of the fluid and $\vec{A} = gh$ is the geopotential, where q is the gravitational constant and $h > 0$ the depth of the fluid above the orography. The problem is defined on the domain $x \geq [0, L]$, with periodic boundary conditions, and we let $t \geq [0, T]$.

The model is discretized using a two-time-level semi-implicit semi-Lagrangian scheme. Further details of the numerics can be found in [6]. We use a periodic domain of 1000 grid points, with a spacing $x = 0.01$ m, so that $x \, 2 \, [0 \, m/10 \, m]$. The model time step is taken to be 9.2 \pounds 10⁻³ s and we consider an assimilation over a window of 100 time steps.

In order to test the assimilation we run 'identical twin' experiments, in which observations are generated from a run of the model defined to be the truth. These observations are then assimilated using 4D-Var, starting from an incorrect prior estimate. The inner minimization is performed using a conjugate gradient method and is considered to

Again it is possible to provide a theoretical understanding of these results by an analysis of the (PGN) method. The method can be considered as a way of solving the approximate normal equations

$$
\tilde{\mathbf{J}}(\tilde{\mathbf{x}}^*)^T \mathbf{f}(\tilde{\mathbf{x}}^*) = 0. \tag{14}
$$

Then based on the work of [7] and [8] we can prove the following theorem:

Theorem 2 Let the first derivative of $\tilde{J}(x)^T f(\tilde{x})$ be written

$$
\tilde{\mathbf{J}}(\mathbf{x})^T \mathbf{J}(\mathbf{x}) + \tilde{Q}(\mathbf{x})
$$
\n(15)

where $\tilde{Q}(x)$ represents second order terms arising from the derivative of $\tilde{J}(x)$. Suppose that on each iteration k
