2 Estimating the observation error covariance matrix with the ensemble transform Kalman filter

Data assimilation techniques combine observations $\mathbf{y}_n = \mathsf{R}^{N^p}$ at time \mathbf{t}_n with a model prediction of the state, the background $\mathbf{x}_n^f = \mathsf{R}^{N^m}$, which is often determined by a previous forecast. The observations and background are weighted by their respective errors, to provide a best estimate of the state $\mathbf{x}_n^a = \mathsf{R}^{N^m}$, known as the analysis. This analysis is then forecast using the possibly non-linear model \mathbf{M}_n to provide a background at the next assimilation time,

$$\mathbf{x}_{n+1}^f = \mathbf{M}_n(\mathbf{x}_n^a). \tag{1}$$

We now give a brief overview of the ensemble transform Kalman filter (ETKF) [Bishop et al., 2001, Livings et al., 2008] that we will adapt and the notation that is used in this study. At time \mathbf{t}_n we have an ensemble, a statistical sample of N state estimates $\{\mathbf{x}_n^i\}$ for $\mathbf{i}=1\dots N$. These ensemble members are stored in a state ensemble matrix $\mathbf{X}_n = \mathbf{R}^{N^m \times N}$ where each column of the matrix is a state estimate for an individual ensemble member,

$$\mathbf{X}_n = \left(\begin{array}{ccc} \mathbf{x}_n^1 & \mathbf{x}_n^2 & \dots & \mathbf{x}_n^N \end{array} \right). \tag{2}$$

It is possible to calculate the ensemble mean,

$$\bar{\mathbf{x}}_n = \frac{1}{\mathsf{N}} \sum_{i=1}^N \mathbf{x}_n^i, \tag{3}$$

and subtracting the ensemble mean from the state ensembles gives the ensemble perturbation matrix

$$\mathbf{X}_n = \left(\begin{array}{ccc} \mathbf{x}_n^1 - \bar{\mathbf{x}}_n & \mathbf{x}_n^2 - \bar{\mathbf{x}}_n & \dots & \mathbf{x}_n^N - \bar{\mathbf{x}}_n \end{array} \right). \tag{4}$$

This allows us to write the ensemble covariance matrix as

$$\mathbf{P}_n = \frac{1}{\mathbf{N} - 1} \mathbf{X}_n \mathbf{X}_n^T. \tag{5}$$

For the ensemble transform Kalman filter (ETKF) the analysis at time t_n is given by,

$$\bar{\mathbf{x}}_n^a = \bar{\mathbf{x}}_n^f + \mathbf{K}_n (\mathbf{y}_n - \mathbf{H}_n (\bar{\mathbf{x}}_n^f)), \tag{6}$$

where $\bar{\mathbf{x}}_n^a$ is the analysis ensemble mean and $\bar{\mathbf{x}}_n^f$ is the forecast ensemble mean. The possibly non-linear observation operator $\mathbf{H}: \mathbf{R}^{N^p} - \mathbf{R}^{N^m}$ maps the state space to the observation space . The Kalman gain matrix,

$$\mathbf{K}_n = \mathbf{P}_n^f \mathbf{H}_n^T (\mathbf{H}_n \mathbf{P}_n^f \mathbf{H}_n^T + \mathbf{R}_n)^{-1} \tag{7}$$

is a matrix of size $\mathbf{N}^m \times \mathbf{N}^p$ where \mathbf{H}_n is the observation operator linearised about the background state. The observation error covariance matrix is denoted by $\mathbf{R}_n = \mathbf{R}^{N^p \times N^p}$ and $\mathbf{P}_n^f = \mathbf{R}^{N^m \times N^m}$ is the forecast error covariance matrix. When the forecast error covariance is derived from climatological data and assumed static, it is often denoted as \mathbf{B}_n and known as the background error covariance matrix.

Previously it has been assumed that the observation error covariance matrix ${\bf R}$ is diagonal. However, with recent work showing that ${\bf R}$

To create observations we must add errors from a specified dis

KS equation are given in Cox and Matthews [2000] and Kassam and Trefethen [2005]. The truth is de ned by the solution to the KS equation on the perio dic domain 0

spread. If the ensemble spread is not maintained the analysiand the estimation of the observation error covariance matrix may be a ected.

4.1 Results with a static R and frequent observations

We begin by considering the case when the true observation wer covariance matrix is static.

In Experiments 1L and 1K we use the standard EKTF for the assimilation. We begin by setting the true matrix R^t to $R^t = R^D + R^C$, where $R^D = 0:1I$ and $R^C = 0:1C$. The Lorenz '96 and KS models are each run for 1000 assimilation sps. We assume that R is diagonal, with $R_0 = \text{diag}(R^t)$. The standard ETKF is used to gain an estimate of R after the assimilation. The background and analysis innovations are calculated throughout the assimilation window. After the nal assimilation these

covariance matrix to be calculated.

We showed it is possible to obtain a good estimate of using the DBCP diagnostic. We then showed that estimating R within the ETKF worked well, with good estimates obtained, the ensemble spread maintained and the analysis MRSE reduced compared to the case where the matrixR is always assumed diagonal. We also showed that the method does not work as well where the observations are less frequenalthough this may be dependent on the model. However the method still produces ae asonable estimate of R, maintains the ensemble variance and the time-averaged anyasis RMSE is lower than where a diagonal R is used.

We next considered a case where varied slowly with time. We showed that the method worked well where the true R was de ned to slowly vary with time. The time-averaged analysis RMSE was low and the ensemble spread was maintained The estimates of the correlation structure were good, suggesting that the methd is capable of estimating a slowly time-varying observation error covariance matrix. A case where the length-scale of the observation error covariance varied more quickly was also considered, and the ETKFR produced reasonable estimates of the observation error cariance matrix. We also showed that the ability of the method to approximate the correlation structure was not sensitive to the forecast error variances or the true magnitude of the observation error variance. This suggests that the method would be suitable to give a time-depndent estimate of correlated observation error. We note that the e ectiveness of the method will depend on how rapidly the synoptic situation and hence correlated error is changing and how often observations are available. The correlated error will also be dependent on the dynamical system. For models designed to capture rapidly developing situations, where epresentativity error and hence correlated error is likely to change rapidly, assimilation cycling and observation frequency within the assimilation is expected to be more frequent and lence more data is available for estimating the observation error.
